ABSTRACT

This paper calculates effective tariffs by economic sector for Brazil from 2000 to 2015. The effective tariff differs from the nominal tariff in that it takes into consideration the protection given to inputs along the production chain. A sector whose products are protected by high tariffs may also be burdened by high tariffs on its inputs, leading to a lower effective tariff. Two series are calculated: 2000 to 2009 and 2010 to 2015. The reason for this is that the National Accounts changed their classification of economic sectors in 2010. Results indicate that: *i*) effective rates of protection are highly varied in Brazil, according to sector; *ii*) effective rates of protection have become slightly more homogeneous in the 15 years from 2000 to 2015; and *iii*) some sectors have seen their rates of protection vary considerably over this fifteen-year period, but most did not.

Keywords: trade policy; effective rates of protection; nominal rates of protection.

1 INTRODUCTION

The impact of tariff structure upon the producers of a given product depends not only on the nominal tariff levied upon the importation of that product, but also on the tariffs of all the inputs that are part of its production chain. A tariff applied upon the import of a given class of product will give its domestic producers an advantage, since it will shield them from import competition. Tariffs levied upon that product's inputs, on the other hand, will result in a higher cost for the producers since they will pay more for these inputs.

The effective tariff rate considers both of these effects. Its calculation consists of subtracting from the tariff rate on the final product the tariffs levied upon its inputs. The comparative analysis of effective protection rates shows us how changes in the tariff structure and the structure of the economy may result in higher or lower protection for each sector, often quite different from the nominal protection rates.

The study of effective protection rates is particularly important when considering regional or sectoral impacts. The impact of tariffs upon labor market outcomes varies according to both the tariff structure and the production chains relevant to each region or sector. In this paper, we will analyze only differences between economic sectors in Brazil during the 2000 to 2015 period. We will not study regional differences.

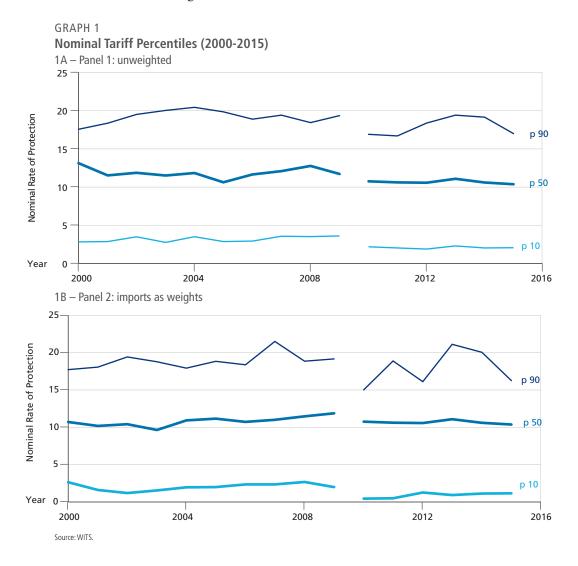

The main objective of this paper is to describe the methodology used to calculate the effective tariff by economic sector. We will also calculate effective tariff rates for economic sectors from 2000 to 2015 using the Input Output Matrices from the National Accounts.

2 METHODOLOGY

Up to the end of the Eighties, Brazilian commercial policy had made extensive use of non-tariff barriers, which limited or outright prohibited the importation of products that competed with national production (Kume, Piani and Souza, 2003). The beginning of the Nineties saw a rapid transition in Brazilian trade policy and non-tariff barriers were largely substituted by a tariff structure decided upon by the 1991 Tariff

Reform and the Mercosur Common External Tariff (TEC). Although there have been some changes in individual tariffs since the Nineties, *grosso modo*, the tariff structure is more or less the same (Castilho, 2015).

Graph 1, below, shows selected percentiles of the Brazilian tariff distribution from 2000 to 2015. The percentiles are p10, p50 (the median tariff), and p90 and there are two panels. The first panel (on the left since we are writing in English and not Arabic or Hebrew) shows the percentiles calculated using an unweighted tariff distribution in which each sector is "worth" the same as any other sector. The second panel (on the right) shows the same statistics calculated using a tariff distribution in which imports (in R\$) are used as the weight of each sector's tariff.

8

Graph 1 shows in visual terms what Castilho (2015) states: while there are definitely changes in individual tariffs, the tariff structure as a whole stays more or less the same over the period.

Nevertheless, the effective protection for some sectors or production chains has changed considerably since the tariff reform of the Nineties. Marta Castilho (2015) states that while there have been no major changes in tariff policy, the effective tariff enjoyed by various sectors has changed over time. These variations can be attributed to some changes in individual product nominal tariffs but also to changes in the structure of the economy such as technical changes and expansion of global value chains.

Castilho (2015) notes that the evolution of effective tariffs has an impact upon the incentive given to various production chains in the Brazilian economy. This happens because the effective tariff depends not only upon nominal tariffs, but also upon the Input Output Matrix, which changes with time. Let us see how.

2.1 ERP Formula

According to Balassa (1965) the effective protection e_j of product j can be calculated using the following formula:

$$e_{j} = \frac{(t_{j} - \sum a_{ij}t_{ij})}{(1 - \sum a_{ij})} \tag{1}$$

According to Equation (1), effective protection is equal to the nominal tariff of the product being protected (t_j) minus the tariffs of all the inputs (t_i) weighted by their relative importance in the product's production chain (a_{ij}) . The intuition is clear: a product is more highly protected if its inputs are not.

Corden (1966; 1971) shows that under reasonable assumptions on substitution of inputs, equation (1) above is equivalent to the following formula:

$$e_{j} = \frac{(Vd_{j} - Vw_{j})}{Vw_{j}} \tag{2}$$

Equation (2) calculates effective protection using the difference between value added with (Vd) and without (Vw) protection of product j.

We will use the first equation in this article because the value added of each product can be calculated using the technical coefficients a_{ij} , which can be calculated from the Input Output Matrices.

The technical coefficient matrix a_{ij} is calculated using the D matrix (participation of each sector in the production of national products), the Bn matrix (technical coefficients of national inputs) and the Bm matrix (technical coefficients of imported inputs). These matrices are all part of the Input Output Matrix of the National Accounts. So we have:

$$a_{ij} = a_{ii}^d + m_{ii}^d \tag{3}$$

Where:

- a^d_{ij} is the technical coefficient for sector *i* (or for all its products, acquired on the internal market) for the production of (products of) sector *j*. The matrix with the coefficients a^d_{ij} is a product of the multiplication of the *D* and *Bn* matrixes of the National Accounts.¹
- m_{ij}^d is the technical coefficient for imported sector i (products of this sector acquired on the international market) for the production of products of sector j. The matrix with the coefficients m_{ij}^d is a product of the multiplication of the D and Bm matrixes of the National Accounts.

Results should be analyzed in relative terms between economic sectors.

2.2 Data

To calculate effective protection rates, we need data with the same classification structure of the Input Output Matrices in the National Accounts data provided by the Brazilian Institute for Geography and Statistics (*Instituto Brasileiro de Geografia e Estatística* – IBGE):

^{1.} More intuitively, each element a_{ij}^d of the matrix is the sum of the participation of each product of sector i as an input in the production of sector j, weighted by the share of each of these products that is produced by sector i. It is the same for m_{ii}^d , but with imported inputs.

- 2 4 0
 - For the 2000 to 2002 period, we used the 2000 Input Output Matrix, which is disaggregated into 55 economic sectors (110 products);
 - For the 2003 to 2009 period, we used the 2005 Input Output Matrix, whose level of aggregation is the same as the 2000 Input Output Matrix;
 - For the 2010 to 2012 period, we used the 2010 Input Output Matrix, which is disaggregated into 67 economic sectors (127 products);
 - For the 2013 to 2015 period, we used the 2015 Input Output Matrix, also disaggregated into 67 economic sectors (127 products).

We tried to use the Input Output Matrix that was closest to the tariff data for each year, but 2008 and 2009 were analyzed using the 2005 Input Output Matrix due to aggregation of economic sectors.

The WITS platform, provided by the World Bank, supplies tariffs applied by sector according to various sector classification schemes.² We chose to use the Harmonized System (HS) scheme. The HS is popular worldwide and also easily matched with the Mercosur Common Nomenclature (NCM), which is based upon the six-digit HS classification (NCM = HS + 2 digits). After associating HS tariffs with NCM, it is possible (though not trivial) to match tariff data to the economic sector classification of the Input Output Matrices using the IBGE translators.

The calculation of effective protection rates faces two data challenges.

The first and most important is that IBGE calculates Input Output Matrices every five years (during the period we study here, 2000, 2005, 2010 and 2015). This means that effective protection tariffs may "jump" up or down every five years, not because reality changes suddenly, but because measurements are made only every five years. We thought of using moving averages, but the price to pay would be to lose precision in changes of effective protection rates.

^{2.} Tariffs can be aggregated according to simple averages or weighted by import volume. In this paper we chose to use weighted tariffs for computing effective rate of protection. Tables for effective rate of protection using simple average of nominal tariffs can be found in the annex.

Another problem is that by using relatively aggregated classification schemes, we lose information in translation. For example, when more than one sector is associated to a given sector in a more aggregated classification scheme only one sector from the more disaggregated scheme is used and the choice is often arbitrary. The translators are imperfect and by far the most labor-intensive part of the process is matching trade statistics and Input Output Matrix statistics.

3 RESULTS

The effective rates of protection by three-digit economic sector can be found on tables 1 and 2. Very high or very low values are striking because they show exceptional incentive or production conditions:

• The value of the effective tariff is usually higher than that of the nominal tariff. If the two are equal, then the product's tariff multiplied by the value added in previous steps of the production chain is equal to the sum of the value added in previous steps weighted by the nominal tariffs, as shown by the equation below.

$$t_{j} \sum a_{ij} = \sum t_{ij} a_{ij} \tag{4}$$

Equal tariffs for all goods will produce the same effective and nominal tariffs, but other tariff structures may also do so.

- If value added is the same with and without tariff protection, then the effective tariff is zero.
- A negative effective protection rate means that the product is being taxed and not protected. A strongly negative effective tariff may mean that that industry is so efficient that it can take the tariff tax and still remain competitive. It may also mean that it is protected by non-tariff barriers.

Table 1, below shows effective tariffs between 2000 and 2009. The cells are colored so as to show the economic sectors that are most protected (in red) and those most heavily taxed by tariffs on their inputs (in green). Yellow and orange colors indicate in between sectors.

Source: Tarifas Nominais do CAMEX/MDIC; Contas Nacionais do IBGE. Elaborated by the authors.

Our calculations suggest that, in 2015, the following economic sectors were those that enjoyed the highest rates of effective protection (SCN 2010):

- motor vehicles, except parts;
- footwear and leather products;
- textiles;
- apparel and clothing accessories; and
- cleaning products, cosmetics/perfumes and toilet preparations.

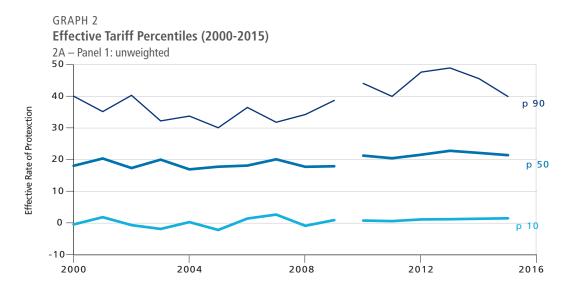

The least protected (or most taxed) economic sectors are:

- coal and non-metallic minerals;
- livestock;
- oil refining and coking plants;
- electricity, natural gas and other utilities; and
- oil and gas.

A striking result is the large swings in effective tariffs over the fifteen years period studied for some sectors. For example, up to 2003, car production was protected by effective barriers close to 200%. By the end of the period, however, the sector's effective tariff had fallen to 90%. The effective tariff on metallurgy of non-ferrous metals likewise varied from -0.8% (2006) to 15.5% (2015) during the period under study. This means that although the Brazilian tariff policy remained roughly constant during the last 15 years, some sectors saw strong variations in their tariffs over this period. Some sectors whose effective tariff suffered high variations during the period are: agricultural pesticides; motor vehicles; alcohol; electricity, gas, water, sewage and urban cleaning; and biofuels.

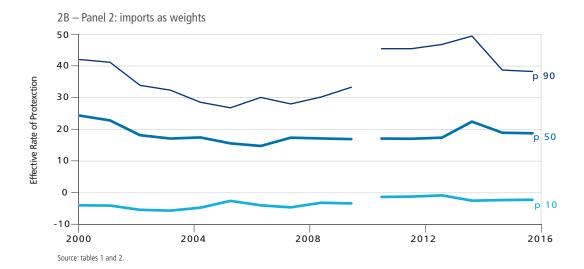

Another result is that there is a visible tendency for the effective tariff rates to become more homogenous over time. While the standard deviation of the effective tariff across economic sectors was close to 24 percentage points during the first half of the first decade of the century, between 2010 and 2015 the same number was under 20 percentage points.

To allow easier visualization of the results in the two tables above, we will repeat graph 1, which was calculated using nominal tariffs, using effective rates of protection. The period is the same (2000 to 2015), as are the percentiles (p10, p50, and p90). On the left, we have the first panel with unweighted percentiles and, on the right, the second with the same statistics calculated using the effective tariff distribution weighted by imports.

16

Graph 2, in comparison with graph 1, shows that effective rates of protection vary much more than nominal rates. The highest effective rates of protection fall around 40%, going to 50% or close on a few years. The median rates are close to 20% (which was the level of the highest rates for nominal protection). The lowest rates are negative or zero. The variation in time is also more pronounced, particularly for the highest tariffs (p90).

4 CONCLUSIONS

Our objective was to update the effective protection calculations made previously for Brazil by various authors such as Castilho (2015) and Kume, Piani and Souza (2003). Due to small methodological differences, the numbers are not directly comparable. The qualitative results, however, can be compared. The main results are the following.

First, there is a large variation in effective protection across economic sectors. In the fifteen years between 2000 and 2015, the highest effective tariff we calculated was 212% and the lowest -11.1%. In general, the least protected sectors are those linked to commodities (usually also export sectors). The most highly protected sectors are all in industry.

Second, there appears to be a trend towards greater homogeneity in effective tariffs, visible in the reduction of the standard error.

Finally, there have been large swings in effective protection rates for some sectors. This is in agreement with the conclusion of Marta Castilho (2015), who states that effective protection rates have not been constant over time.
